

Validation Output: Residential Units

Identified Configuration

From the architectural drawings and standard floor plan visible on the website, each typical floor (Level 2–4) include:

- Approximately 6–8 residential units arranged around a central shared space.

The original estimate:

“Residential units × 6–8 per floor (Level 2–4)”

This was derived from:

- The visible standard floor plan, which showed a layout of 7 identifiable units, based on apartment entrances and stairwells.
- Units are distributed around a central corridor and shared living room, with stairwell and lift access nearby.

Cross-check Based on PREPROCESS Analysis Logic

According to the logic in PREPROCESS `analysis.txt`, Section: “Analysis Logic”:

“Apply the rule to the floor plan confirms that 7 distinct residential unit entries are visible and consistently spaced across the floor plan.”

- Applying that rule to the floor plan confirms that 7 distinct residential unit entries are visible and consistently spaced across the floor plan.

This matches the midpoint of the 6–8 range used previously.

Final Result (English Output)

The estimated count of 6–8 residential units per floor is consistent with the standard floor plan. Upon visual verification using partition lines and door locations, 7 clearly identifiable units are present per floor. Therefore, the previously provided unit count is accurate and conforms to the element identification and quantification defined in the preprocessing output module.
